MINI ASSESSMENT

Name	Gowkanapalle Jayasree
Reg No	99230040927
Department	CSE

1. What is the purpose of checking the response status code before processing API data?

Answer: Checking the response status code helps the program determine whether the API request was successful. For example, a 200 status usually indicates success, while 404 means the requested resource was not found and 500 indicates a server-side error. The program can handle each situation appropriately instead of trying to process invalid data.

2. Why should an API program use a timeout when sending a request?

Answer: A timeout prevents the program from waiting indefinitely if the API server is slow or unavailable. When a timeout occurs, the program can catch the exception and show an error message or retry the request after a suitable delay. This makes the application more reliable and responsive.

3. What is the advantage of using a default value when accessing optional JSON data?

Answer: API responses may sometimes omit optional fields. Using a default value allows the program to continue safely when a key is missing. For example, **data.get('email', 'Not Available')** returns the email when it exists and returns 'Not Available' when it does not. This avoids unnecessary errors and makes the code more robust.
